Note that conditions #1 and #2 in Definition 5.1.1 are required for $(p(x,y))$ to be a valid joint pmf, while the third condition tells us how to use the joint pmf to find probabilities for the pair of random variables $((X,Y))$.

Definition: density function. The probability distribution of a continuous random variable (X) is an assignment of probabilities to intervals of decimal numbers using a function $(f(x))$, called a density function, in the following way: the probability that (X) assumes a value in the interval $(\left[a,b\right])$ is equal to the area of the region that is bounded above by the graph of ...

In this video, we're going to review some basic concepts about random variables that we'll need in the rest of the course. So a random variable is just really any uncertain quantity.

Section 5.1 Random Variables (UE 2.1) Note: This is a combination of Section 5.1 and Undergraduate Econometrics (UE) 2.1. Recall in our discussion on probability we started out with some random experiment that gave rise to our set of all possible outcomes S . We developed some rules for calculating probabilities about various events.

5.1 Two Random Variables The notion of a random variable as a mapping is easily generalized to the case where two quantities are of interest. Consider a random experiment with sample space S and event class F . We are interested in a function that assigns a pair of real numbers X, Y to each

1 Chapter 5 Multiple Random Variables §5.1 Joint Cumulative Distribution Function The joint CDF $F_{X,Y}(x,y) = P[X \leq x, Y \leq y]$ is a complete probability model for any pair of random variables X and Y . Definition 5.1 Joint Cumulative Distribution Function (CDF) $F_{X,Y}(x,y) = P[X \leq x, Y \leq y]$

Chapter 5 Multiple Random Variables

Random Variables can be either Discrete or Continuous: Discrete Data can only take certain values (such as 1,2,3,4,5) Continuous Data can take any value within a range (such as a person's height) All our examples have been Discrete. Learn more at

create random variable while one which takes on a noncountably infinite number of values is called a nondiscrete random variable. Discrete Probability Distributions Let X be a discrete random variable, and suppose that the possible values that it can assume are given by x_1, x_2, x_3, \dots , arranged in some order.

Random Variables and Probability Distributions

So, I would define my (Random) Variable to generate (remember it is a mapper/function) 0 for {TT}, 1 for both {TH} & {HT} and 2 for {HH}. The Random Variables are generally represented using an uppercase letter. For e.g. for above experiment I would write it as $H = \{0,1,2\}$.

1.1 RANDOM VARIABLES 5 The term $\binom{n}{k}$ is the binomial coefficient, and counts the number of ways objects can be chosen from distinct objects. It is defined by $\binom{n}{k} = \frac{n!}{k!(n-k)!}$ where $n!$ is the factorial of n , or $n! = n \cdot (n-1) \cdot \dots \cdot 2 \cdot 1$ Example 8 Binomial tree model for stock prices To be completed. 1.1.2 Continuous Random Variables

RANDOM VARIABLES AND PROBABILITY DISTRIBUTIONS 3.1

Concept of a Random Variable Random Variable A random variable is a function that associates a real number with each element in the sample space. In other words, a random variable is a function $X: S \rightarrow \mathbb{R}$, where S is the sample space of the random experiment under consideration. NOTE.

3.1 Concept of a Random Variable

A random variable is a variable that denotes the outcomes of a chance experiment. For example, suppose an experiment is to measure the arrivals of cars at a tollbooth during a minute period. The possible outcomes are: 0 cars, 1 car, 2 cars, ..., n cars. There are two categories of random variables (1) Discrete

For example, say Xavier, Yoshi, and Zander all take a multiple-choice test by guessing; their scores are the random variables X , Y , and Z . The average $A = \frac{1}{3}(X + Y + Z)$ is a function of the original three random variables and is a brand-new random variable on its own.

1.3.3 Indicator Random Variables Let A be an event. We define the indicator of A , 1_A , to be the random variable $1_A(\omega) = \begin{cases} 1 & \text{if } \omega \in A \\ 0 & \text{if } \omega \notin A \end{cases}$. Observe that 1_A follows the $\text{Ber}(p)$ distribution where $p = \Pr(A)$. An important property of indicator random variables (and Bernoulli random variables) is that $X^k = X$ for any $k \geq 1$.
