Porosity calculation is the third step of well log analysis and it could only be done correctly if the first step (lithology interpretation) is correct. There are many methods that can be used to calculate the porosity, the user may use density log, sonic log, neutron log, or combination between them, but the most common one is neutron-density log combination.

Applied Petrophysics and Well Log Interpretation - RMT

Well logging is an evaluation method in which a logging crew lowers a special tool, a sonde, into the well and then pulls it back up. As the sonde passes the formations on its way up the wellbore, it senses and measures electrical, radioactive, and acoustic (sound) properties of the rocks.

has been remarkable. This is both an asset and a liability. It is an asset for new fields where the most modern technology can be applied. It is a liability for old fields where old logs must be combined with new logs in the analysis of a field.

Log analysts perform quality control on the data and determine what corrections are required before carrying out quantitative analysis of the data. For example, gas, fractures and lack of compaction require corrections to be applied to the sonic log. Lithologies affect the density, neutron and sonic logs.

Facies Interpretation from Well Logs: Applied to SMEKS ...

Well-logs are single point measurements of physical properties of the subsurface recorded in a well and vary vertically with depth. The properties are random and aperiodic and depend on factors like mineral composition or lithology, porosity, cementation and compaction, presence of fluids etc.,

Equations revealed significant similarity in the porosity values obtained from petrophysical well log and core data. Plots on scatter diagrams using porosity values derived from petrophysical log and that from core analysis for the four reservoirs obtained correlation coefficient (r) values of 0.7165, 0.8094, 0.5835, and 0.5025, respectively for
